Aim

Task:

- Investigating the risk factors of HCC in patients undergoing screening from 2009 to 2017 in the South East of Scotland.

Research questions:

- What is the risk of HCC development in populations with different causes of liver disease?
- Is the male/female gender bias in HCC development stronger in some causes of liver disease?
- How strong is the association between AFP levels and the risk of HCC?
- Can the observed AFP levels provide prediction on survival probabilities?

● Conclusion

The dataset

Screening and HCC cohort

- 1 Patient in screening (1506)
- 2 Patient in HCC (240)
- 3 $\log_{10}(\text{AFP})$ measures [1]
- 4 Covariates
 - ▶ Age at sample
 - ▶ Observation time
 - ▶ Time to event
 - ▶ Gender
 - ▶ Aetiology
 - ▶ Status

Data in HCC cohort

The modelling approach

- Aim
- Data description
- **Methodology**
 - Survival submodel
 - Longitudinal submodel
 - Joint model
- Results
- Discussion
- Conclusion

- 1 Cox proportional hazards model as survival function estimator to estimate the survival probability over time [2].
- 2 Linear mixed-effect model is used to fit and predict the evolution of the biomarker over time for each patient.
- 3 Combine both method to obtain a joint model which can measure the association of the AFP measures and the risk of HCC [3].

Univariate Cox regression

$$h_i(t | w_i) = \lim_{dt \rightarrow 0} \frac{\Pr[t \leq T^* < t + dt \mid T^* \geq t, w_i]}{dt}$$

$$= h_0(t) e^{\gamma^T w_i}$$

Table: Coefficient estimates of the Cox model

	beta	Hazard Ratio (95% CI)	p-value
Sex	-0.68	0.51 (0.37-0.69)	1.4e-05
Age	1.6	5.2 (3.7-7.1)	0
ALD	0.73	2.1 (1.6-2.7)	2e-07
NAFLD	1.1	3.2 (2.3-4.4)	7.7e-12
HepB	-1.3	0.27 (0.12-0.6)	0.0015
HepC	-0.18	0.83 (0.62-1.1)	0.24

- Aim

- Methodology
 - Survival submodel
 - Longitudinal submodel
 - Joint model
- Results
- Discussion
- Conclusion

Multivariate Cox regression

Multivariate Cox regression

Survival curve for each aetiology

- ALD, NAFLD and Hepatitis C suffering patients more at risk of developing HCC.

Multivariate Cox regression (continue)

Survival probabilities difference between male and female

- Female survival outcome better than males.
- Median survival rate of women between 1 to 3 years greater than men.
- Gender bias for HCC more pronounced in ALD, NAFLD and Hepatitis C compared to Hepatitis B and autoimmune diseases.

Linear mixed-effects model

$$\begin{cases} y_i(t) = m_i(t) + \epsilon_i(t), \\ m_i(t) = x_i^T(t)\beta + z_i^T b_i, \\ b_i \sim N(0, D), \quad \epsilon_i(t) \sim N(0, \sigma^2), \end{cases}$$

where

- $x_i(t)$ and β are the Fixed-effects part of the model
- $z_i(t)$ and b_i are the Random-effects part of the model

- 1 $\beta + b_i$ describes individual response trajectories
- 2 Can obtain different average longitudinal evolution per aetiology.
- 3 can accommodate the fact that patients have different number of repeated measurements.

 - Survival submodel
 - Longitudinal submodel
 - Joint model
- Results
- Discussion
- Conclusion

Joint model

The intuitive idea behind Joint models

- The evolution of the biomarker over time, $m_i(t)$ is described by the longitudinal model.
- We can use the estimated evolutions in a Cox model.
- The two models are combined to estimate their joint distribution.

The longitudinal submodel

$$\left\{ \begin{array}{l} y_i(t) = m_i(t) + \epsilon_i(t), \\ m_i(t) = (\beta_0 + b_{i0}) + (\beta_1 + b_{i1})B_n(t, 3) + \beta_2 \text{ Sex} \\ \quad + \beta_3 \text{ Age}_i + \beta_4 \text{ ALD}_i + \beta_5 \text{ NAFLD}_i \\ \quad + \beta_6 \text{ HepB}_i + \beta_7 \text{ HepC}_i, \\ b_i \sim N(0, D), \quad \epsilon_i(t) \sim N(0, \sigma^2), \end{array} \right.$$

Joint model (continue)

The survival submodel

$$h_i(t \mid M_i(t), w_i) = h_0(t) e^{\gamma^T w_i + \alpha_1 m_i(t) + \alpha_2 \frac{d m_i(t)}{dt}} \quad \text{where}$$

$$\begin{aligned} \gamma^T w_i = & \gamma_1 + \gamma_2 \text{Age}_i + \gamma_3 \text{ALD}_i + \gamma_4 \text{NAFLD}_i \\ & + \gamma_5 \text{HepB}_i + \gamma_6 \text{HepC}_i \end{aligned}$$

- $M_i(t)$ is the longitudinal measurement history of the biomarker.
- α quantifies the strength of the association between $\log(\text{AFP})$ levels and risk of HCC.
- w_i , the different predictors at baseline.

Joint model (continue)

The joint model distribution [4]

$$p(T_i, \delta_i, y_i) = \int p(y_i | b_i) \{h(T_i | b_i)^{\delta_i} S(T_i | b_i)\} p(b_i) db_i$$

- $S(\cdot)$ denotes the survival function and $p(\cdot)$ the density function.
- estimation is done under the Bayesian approach (MCMC)

posterior distribution

$$p(\theta, \mathbf{b}) \propto \prod_{i=1}^n \prod_{l=1}^{n_i} p(\mathbf{y}_i | \mathbf{b}_i, \theta) p(T_i, \delta_i | \mathbf{b}_i, \theta) p(\mathbf{b}_i | \theta) p(\theta)$$

- Conclusion

Joint model (continue)

Table: Coefficient estimates for the Cox survival submodel

	Value	Std.Err	Std.Dev	2.5%	97.5%	P
Sex	-0.837	0.013	0.183	-1.188	-0.476	0
Age	0.095	0.002	0.007	0.080	0.106	0
ALD	0.789	0.011	0.159	0.494	1.117	0
NAFLD	0.533	0.013	0.198	0.136	0.922	0.001
HepB	0.298	0.032	0.446	-0.603	1.126	0.510
HepC	0.771	0.016	0.192	0.382	1.154	0
Assoct	1.930	0.005	0.094	1.747	2.111	0
AssoctE	0.252	0.079	3.102	-5.954	6.225	0.009
tauBs	66.612	8.017	71.051	3.522	259.697	

- The intercept and slope of the biomarker trajectory are highly associated with the risk of HCC.
- one unit in $\log(\text{AFP})$ increases the risk of HCC by 29%.

Limitations and further work

Limitations

- Informative censoring mechanism: the probability of a subject being censored depends on the failure process.
- Proportional hazard assumption: explanatory variable acts multiplicatively on the hazard ratio (not directly on the failure time)

Further work

- Multiple Longitudinal Markers (e.g platelet, DCP treatment, etc ...)
- Imputation of missing data
- correction for potential selection bias due to loss to follow up (e.g inverse probability-of-censoring weighted estimation)

Conclusion

- ALD, NAFLD and Hepatitis C suffering patients more at risk of developing HCC.
- median survival time 9.5 years vs 13 years for "Other" category.
- gender bias in developing HCC more pronounced in ALD, NAFLD and Hepatitis C compared to other aetiologies.
- The intercept and slope of the biomarker trajectory are highly associated with the risk of HCC.
